Localization in Algebra

Localization: systematically adjoin multiplicative inverses

Setup: $R =$ ring, $S \subset R$ multiplicatively closed

Get: $S^{-1}R = R \times S / \sim$, e.g. $(\mathbb{Z}^\times)^{-1}\mathbb{Z} = \mathbb{Q}$, $\langle 2 \rangle^{-1}\mathbb{Z} = \mathbb{Z}_{(2)}$

Also get: universal ring homomorphism $R \rightarrow S^{-1}R$ taking S to units, i.e. for any $f : R \rightarrow E$ taking S to units

$\exists ! g$ making diagram commute:

$$\begin{array}{ccc} R & \xrightarrow{i} & S^{-1}R \\ \downarrow f & \searrow g & \\ E & & \end{array}$$

How to generalize to categories? (No mult. inverses)

Inverting s is the same as inverting the map $\mu_s(r) = s \cdot r$

Localization in Categories

Setup: \mathcal{C} = category, T = set of morphisms. Get: $\mathcal{C}[T^{-1}]$ and universal $\mathcal{C} \rightarrow \mathcal{C}[T^{-1}]$ taking T to isomorphisms.

$$\begin{array}{ccc} \mathcal{C} & \longrightarrow & \mathcal{C}[T^{-1}] \\ \downarrow & \nearrow \text{dashed} & \\ \mathcal{D} & & \end{array}$$

$$\text{obj}(\mathcal{C}[T^{-1}]) = \text{obj}(\mathcal{C})$$

Example: $\text{Top}\{(\text{homotopy equivalences})^{-1}\} = \text{HoTop}$

Adjoining f^{-1} forces us to adjoin many $g \circ f^{-1}$ & $f^{-1} \circ h$

$$\mathcal{C}[T^{-1}](X, Y) = \text{Zigzags} / \sim$$

Oops! Zigzags is not a set

Model Categories

Can't localize an arbitrary \mathcal{C} at an arbitrary T

Let $\mathcal{C} = \mathcal{M}$ have all small (co)limits and distinguished classes of maps $\mathcal{W}, \mathcal{F}, \mathcal{Q}$ satisfying some axioms.

Called: weak equivalences, fibrations (e.g. $F \rightarrow E \rightarrow B$), cofibrations (e.g. satisfying homotopy extension property)

If we set $T = \mathcal{W}$ then $\mathcal{M}[\mathcal{W}^{-1}] = \text{Ho}(\mathcal{M})$ exists and has the desired universal property

Some model categories: Spaces, Spectra, $\text{Ch}(R)$, G -spectra (many model category structures)

(Left) Bousfield Localization

Suppose we want to invert $f \notin \mathcal{W}$. Because $\mathrm{Ho}(\mathcal{M})$ is nice:

$$\begin{array}{ccc}
 \mathcal{M} & \xrightarrow{\quad \dots \quad} & \boxed{L_f \mathcal{M}} \\
 \downarrow & & \downarrow \\
 \mathrm{Ho}(\mathcal{M}) & \longrightarrow & \mathrm{Ho}(\mathcal{M})[f^{-1}]
 \end{array}
 \qquad
 \begin{array}{l}
 \mathrm{obj}(L_f \mathcal{M}) = \mathrm{obj}(\mathcal{M}) \\
 L_f \mathcal{M}(X, Y) = \mathcal{M}(X, Y)
 \end{array}$$

Under standard hypotheses on \mathcal{M} , $L_f \mathcal{M} = \text{model category}$.

$$\mathcal{W}_f = \langle f \cup \mathcal{W} \rangle \supset \mathcal{W}, \mathcal{Q}_f = \mathcal{Q}, \mathcal{F}_f \subset \mathcal{F}$$

Note: localizing a set T of maps is the same as localizing

$f = \coprod_{g \in T} g$, so it's fine to look at just L_f

A question

L_f preserves many standard properties of model categories. Does it preserve monoids? Yes for A_∞ and E_∞ . No for strict commutative (Hill, 2011). Goal: Figure out when it does

Given associative $\otimes : \mathcal{M} \times \mathcal{M} \rightarrow \mathcal{M}$ with unit S , a monoid E has $\mu : E \otimes E \rightarrow E$, $\eta : S \rightarrow E$, commutative diagrams

$$\begin{array}{ccc} E \otimes E \otimes E & \longrightarrow & E \otimes E \\ \downarrow & & \downarrow \\ E \otimes E & \longrightarrow & E \end{array} \qquad \begin{array}{ccccc} S \otimes E & \longrightarrow & E \otimes E & \longleftarrow & E \otimes S \\ & \searrow & \downarrow & \swarrow & \\ & & E & & \end{array}$$

Morally: $a(bc) = (ab)c$ and $1 \cdot a = a = a \cdot 1$

Commutative E also has twist $\tau : E \otimes E \rightarrow E \otimes E$.

Monoidal Model Categories

- 1 Pushout Product Axiom: Given $f : A \rightarrow B$ and $g : X \rightarrow Y$ cofibrations, $f \square g$ is a cofibration. If $f \in \mathcal{W}$ then $f \square g \in \mathcal{W}$.

$$\begin{array}{ccc}
 A \otimes X & \longrightarrow & B \otimes X \\
 \downarrow & \Downarrow & \downarrow \\
 A \otimes Y & \longrightarrow & P \\
 & \searrow & \downarrow f \square g \\
 & & B \otimes Y
 \end{array}$$

The diagram illustrates the Pushout Product Axiom. It shows a commutative square with a pushout P at the bottom right. The top row is $A \otimes X \rightarrow B \otimes X$. The left vertical arrow is $A \otimes X \rightarrow A \otimes Y$. The right vertical arrow is $B \otimes X \rightarrow P$. The bottom horizontal arrow is $A \otimes Y \rightarrow P$. A curved arrow goes from $A \otimes X$ to $B \otimes Y$. Another curved arrow goes from P to $B \otimes Y$, labeled $f \square g$. A double arrow \Downarrow indicates the square is a pushout.

- 2 Unit Axiom: For cofibrant X , $QS \otimes X \rightarrow S \otimes X \cong X$ is in \mathcal{W}
- 3 Monoid Axiom: Transfinite compositions of pushouts of maps in $\{\text{Trivial-Cofibrations} \otimes id_X\}$ are weak equivalences.

Preservation of Strict Monoids

- (1) & (2) $\Rightarrow \text{Ho}(\mathcal{M})$ is monoidal (\otimes is a Quillen bifunctor)
(3) implies the monoids $\text{Mon}(\mathcal{M})$ form a model category.

$X \in \text{Ho}(\mathcal{M})$ is a *strict monoid* if there is a monoid $R \in \mathcal{M}$ commuting “on the nose” such that $R \cong X$ in $\text{Ho}(\mathcal{M})$.

Localization *preserves strict monoids* if the composition $\text{Ho}(\mathcal{M}) \rightarrow \text{Ho}(L_f \mathcal{M}) \rightarrow \text{Ho}(\mathcal{M})$ takes X to a strict monoid

Theorem

If $L_f \mathcal{M}$ satisfies (1)-(3) then L_f preserves strict monoids

$L_f \mathcal{M}$ can fail Pushout Product Axiom: $\mathcal{M} = \mathbb{F}_2[\Sigma_3]\text{-mod}$ and $f : \mathbb{F}_2 \rightarrow \mathbb{F}_2 \oplus \mathbb{F}_2 \oplus \mathbb{F}_2$ taking 1 to $(1, 1, 1)$

Preservation of Monoidal Structure

The Unit Axiom is trivially preserved by L_f because $Q_f = Q$

Theorem

*If \mathcal{M} is a cofibrantly generated, left proper, monoidal model category with cofibrant objects flat and generating (trivial) cofibrations I and J having cofibrant domains, and if $f \otimes K$ is an f -local equivalence for all (co)domains K of maps in $I \cup J$, **then** $L_f \mathcal{M}$ **is a monoidal model category** with cofibrant objects flat and domains of $I_f \cup J_f$ cofibrant.*

Theorem

*Assuming further that \mathcal{M} is weakly finitely generated, that f has SSet-small (co)domain, and a technical condition on $Q \otimes -$, then $L_f \mathcal{M}$ **satisfies the monoid axiom**.*

Preservation of Strict Commutative Monoids

Theorem

If $L_f \mathcal{M}$ is a monoidal model category with $\text{CommMon}(L_f \mathcal{M})$ a model category, then L_f preserves strict commutative monoids

John Harper suggested a Σ_n -equivariant monoid axiom :
Transfinite compositions of pushouts of maps $J^{\square n} \otimes_{\Sigma_n} id_X$ are in $\mathcal{W} \ \forall X$

This gets $\text{CommMon}(-)$ to be a model category, and should work for more general coloured operads

Next: L_f preserves Σ_n -equivariant monoid axiom

After that: Applying results to examples, especially G -spectra.
